

# Sorting Algorithms

1. Selection
2. Bubble
3. Insertion
4. Merge
5. Quick

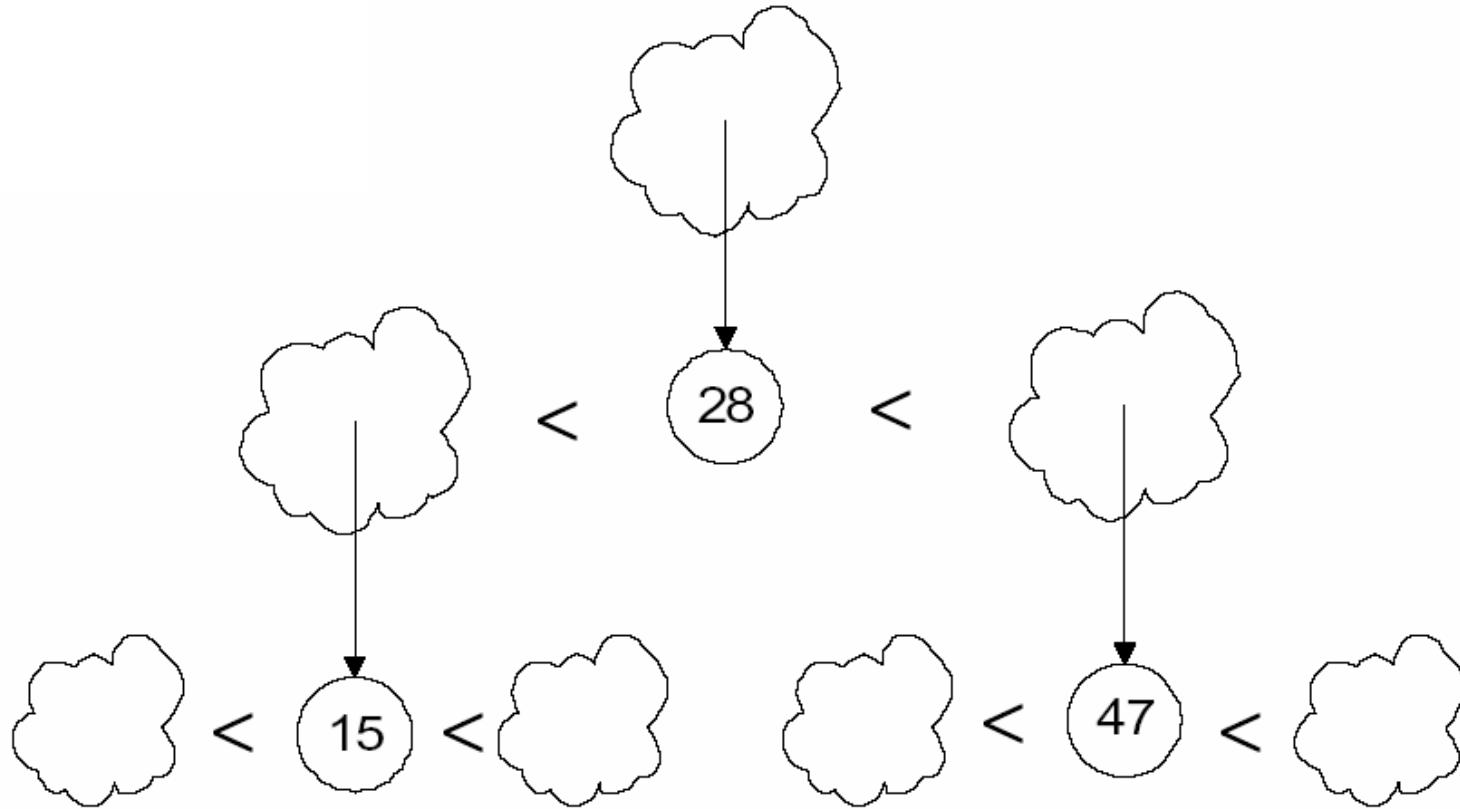

# Sorting algorithms

- Insertion, selection and bubble sort have quadratic worst-case performance
- The faster comparison based algorithm ?

$O(n \log n)$

- Mergesort and Quicksort

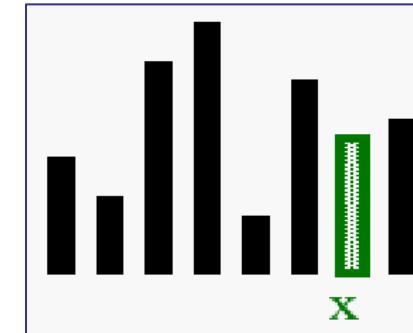

# Idea of Quicksort

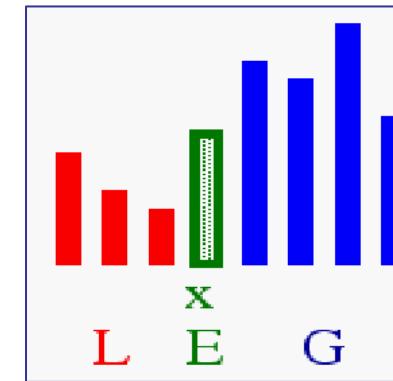

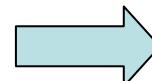

Pick a “pivot”. Divide into less-than & greater-than pivot.  
Sort each side recursively.

# Idea of Quicksort

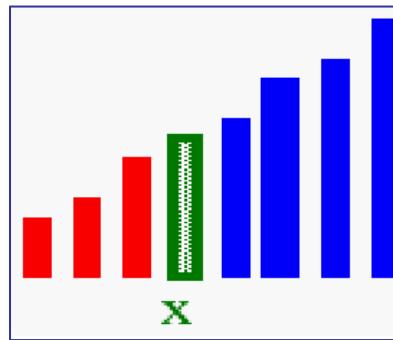

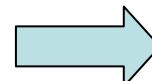

1. **Select:** pick an element

2. **Divide:** rearrange elements so that **x goes to its final position E**

3. **Recur and Conquer:** recursively sort

# Quicksort Algorithm

Given an array of  $n$  elements (e.g., integers):

- If array only contains one element, return
- Else
  - pick one element to use as *pivot*.
  - Partition elements into two sub-arrays:
    - Elements less than or equal to pivot
    - Elements greater than pivot
  - Quicksort two sub-arrays
  - Return results

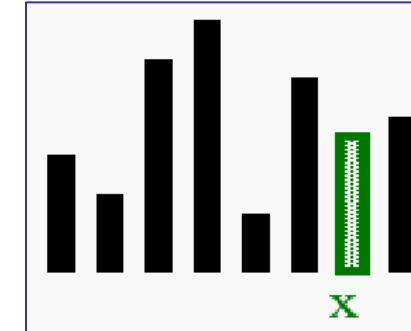

# Example

We are given array of n integers to sort:

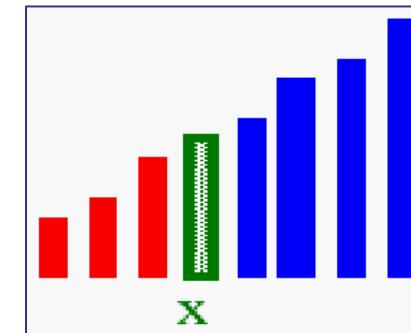

40	20	10	80	60	50	7	30	100
----	----	----	----	----	----	---	----	-----

# Idea of Quicksort

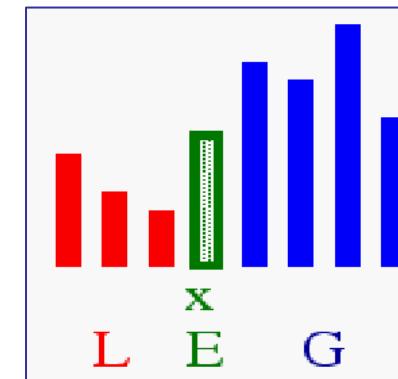

1. **Select:** pick an element

2. **Divide:** rearrange elements so that **x** goes to its final position **E**

3. **Recur and Conquer:** recursively sort

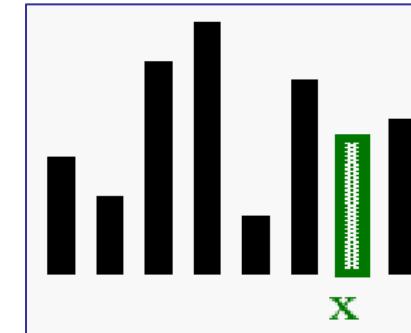

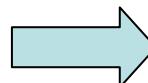

# Pick Pivot Element

- There are a number of ways to pick the pivot element. In this example, we will use the first element in the array:

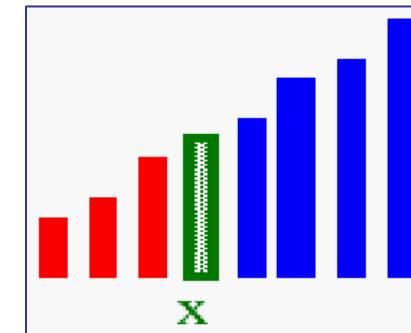

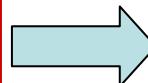

40	20	10	80	60	50	7	30	100
----	----	----	----	----	----	---	----	-----

# Idea of Quicksort

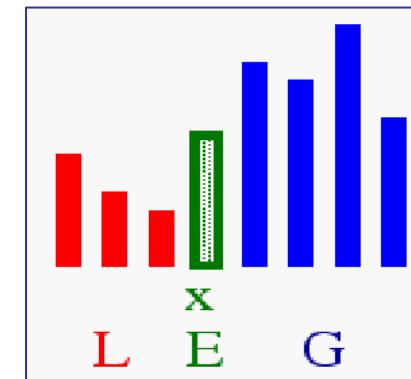

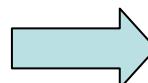

1. **Select:** pick an element

2. **Divide:** rearrange elements so that **x** goes to its final position **E**

3. **Recur and Conquer:** recursively sort

# Partitioning Array

- **Given a pivot, partition the elements of the array such that the resulting array consists of:**
  - One sub-array that contains elements  $\geq$  pivot
  - Another sub-array that contains elements  $<$  pivot
- **The sub-arrays are stored in the original data array.**
- **Partitioning loops through, swapping elements below/above pivot.**

4. While  $\text{too\_small\_index} > \text{too\_big\_index}$ , go to 1.
5. Swap  $\text{data}[\text{too\_small\_index}]$  and  $\text{data}[\text{pivot\_index}]$

# Quicksort Analysis → Average Case

- Complicated proof using recurrences
- If the pivot is chosen at random, what is its average expected value?
- About the median of all values in that part of the array
- Hence on average the array is split in about equal parts
- Hence quicksort in the average case behaves as in the best case:  $O(N \log N)$ .

# Quicksort Analysis

- **Best** case running time:  $O(n \log_2 n)$
- **Worst** case running time:  $O(n^2)$
- **Average** case running time:  $O(n \log_2 n)$

# Summary of Sorting Algorithms

Algorithm	Time	Notes
selection-sort	$O(n^2)$	<ul style="list-style-type: none"><li>• in-place</li><li>• slow (good for small inputs)</li></ul>
insertion-sort	$O(n^2)$	<ul style="list-style-type: none"><li>• in-place</li><li>• slow (good for small inputs)</li></ul>
quick-sort	$O(n \log n)$ expected	<ul style="list-style-type: none"><li>• in-place, randomized</li><li>• fastest (good for large inputs)</li></ul>
merge-sort	$O(n \log n)$	<ul style="list-style-type: none"><li>• sequential data access</li><li>• fast (good for huge inputs)</li></ul>

# Mergesort X Quicksort

- **Mergesort**
  - Splits partitions in half
  - Merges smaller lists back into larger list
  - Requires overhead when sorting arrays
- **Quicksort**
  - Relies on a pivot point for sorting
  - Smaller sets are sorted based on pivot point
  - Can perform slowly if a bad pivot point is used

# Mergesort X Quicksort

- **Mergesort**
  - Use extra space
  - Is guaranteed to have  $O(n \log n)$  performance in the worst case
- **Quicksort**
  - Does **not** use extra space
  - Is **not** guaranteed to have  $O(n \log n)$  performance in the worst case, unlike merge sort

# Mergesort X Quicksort

- **Advantages of quicksort over mergesort**
  - Quicksort doesn't require an extra array
  - the hidden constant in the average case for quicksort is smaller than the hidden constant for merge sort.
- **Advantage of mergesort over quicksort:**
  - better worst case behavior
- **Quicksort and mergesort are optimal, in the sense that a general sorting algorithm cannot do better than average case  $O(n \log n)$ .**

# Mergesort X Quicksort

- Both QuickSort and MergeSort are  $O(n \log n)$  for their average cases.
- However, the characteristic of 'O' notation is that you drop all constant factors.
- Therefore, one  $O(n)$  algorithm could take 1000 times as long as another  $O(n)$  algorithm, and as long as the complexity isn't dependant on the size on 'n', they're both  $O(n)$  algorithms.

# Mergesort X Quicksort

- The advantage of QSort over MergeSort is that it's constant factor is smaller than MergeSort's, and so therefore, on the average case, it is faster (**but not less complex**).
- Empirically, QSort is best, especially if the 'pivot' value has been properly selected

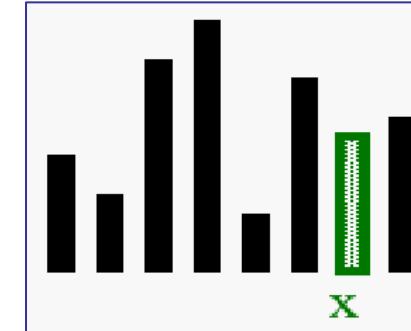

# Quicksort Analysis

- Best case running time:  $O(n \log_2 n)$
- Worst case running time:  $O(n^2)$
- Average case running time:  $O(n \log_2 n)$

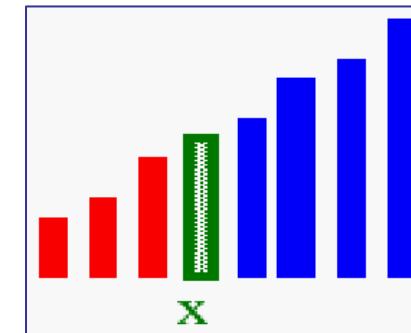

What can we do to avoid worst case?

# Idea of Quicksort

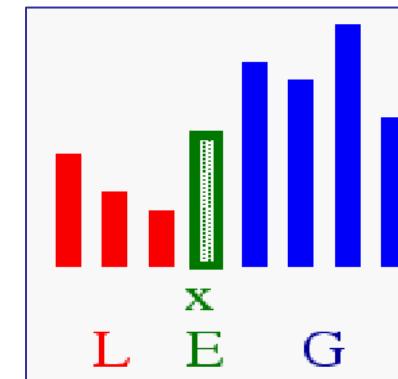

1. **Select:** pick an element

2. **Divide:** rearrange elements so that **x** goes to its final position **E**

3. **Recur and Conquer:** recursively sort

# Choosing the Pivot

- If we happen to pick the pivot which is always the largest or the smallest element, quicksort works just like selection sort
- If we always pick the element with the median value, it splits the array in half at every recursion level
- Hence: best case is  $O(N \log N)$ , worst case quadratic

# Choosing the Pivot

- Pick first, last, or middle element: works fine with random arrays
- Generate a random index
- Pick median value of three elements from data array:  $\text{data}[0]$ ,  $\text{data}[n/2]$ , and  $\text{data}[n-1]$ .
- ...

This algorithm works with two counters, i, j, that count inwards from the left and right, that swap across elements that are the wrong size compared to the pivot, stopping when the pointers cross.

```
void quicksort(int a[], int left, int right)
{
    int i,j,v;

    if(right > left) {
        v = a[right]; i = left - 1; j = right;
        for(;;) {
            while(a[++i] < v) ;
            while(a[--j] > v) ;
            if(i >= j) break;
            swap(a, i, j);
        }
        swap(a, i, right);
        quicksort(a, left, i - 1);
        quicksort(a, i + 1, right);
    }
}
```

This algorithm works with two counters, i, j, that count inwards from the left and right, that swap across elements that are the wrong size compared to the pivot, stopping when the pointers cross.

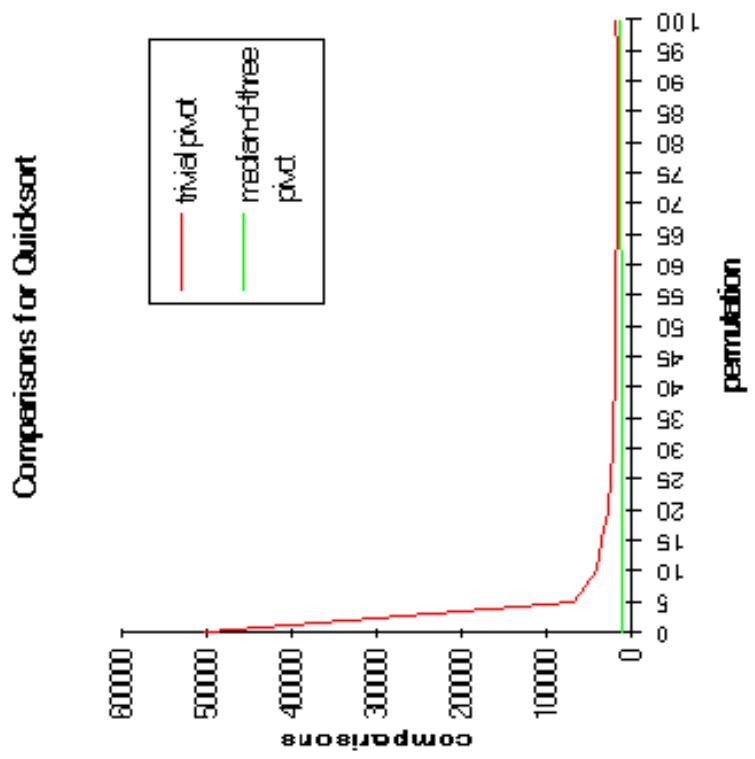

```
void quicksort(int a[], int left, int right)
{
    int i,j,v,m, mid;

    if(right > left) {
        if((right - left) > 3) {
            m = get_median(a, left, right);
            if(m != right)
                swap(a, m, right);
        }
        v = a[right]; i = left - 1; j = right;
        for(;;) {
            while(a[++i] < v) ;
            while(a[--j] > v) ;
            if(i >= j) break;
            swap(a, i, j);
        }
        swap(a, i, right);
        quicksort(a, left, i - 1);
        quicksort(a, i + 1, right);
    }
}
```

Sweaps for Quicksort

Comparisons for Quicksort

# Improving Performance of Quicksort

- Improved selection of pivot.
- For sub-arrays of size 3 or less, apply brute force search:
  - Sub-array of size 1: trivial
  - Sub-array of size 2:
    - if( $\text{data[first]} > \text{data[second]}$ ) swap them
  - Sub-array of size 3: left as an exercise.
